Foam Wedge Support

A piece of foam was cut into a wedge and placed under the dislocated hip when the child was sitting which improved her posture and her ability to use her hands to play. When used in the highchair, she had more support and was able to feed herself more successfully. The wedge was also used under her foot when standing to improve her stability and posture to facilitate easier play at the couch with toys. The wedge was also easy to transport: just throw it in the diaper bag and it could be used in other settings.
